5 WSGI Application

WSGI Application

Most Python web development doesn't occur at the WSGI level. WSGI is designed to move HTTP messages between clients and servers. It intentionally omits higher level functionality which is expected to be provided by a WSGI compliant web framework.

WSGI frameworks such as [Flask](#), [Django](#), and [CherryPy](#), among others include the types of high level features expected in a modern web framework. Features such as: URL path routing, query string parsing, template rendering, etc.

The application created in this step highlights some of the features required to create a more functional web application.

Instructions

1. Stop the WSGI server process.

1. Click anywhere inside the **WSGI terminal** pane to set focus.

2. Press `CTRL+C` to interrupt the process

URL paths are used to locate specific resources on a server. It's commonly up to a web application to determine the structure of URL paths and how they're used to look up resources.

In the URL <https://cloudacademy.com/lab/python-wsgi/> the path of `/lab/python-wsgi/` instructs the server to locate a lab environment named **python-wsgi**.

WSGI applications commonly map specific URL paths to callables used to generate HTTP response messages.

The `Application` class defined in the code below is a WSGI application capable of mapping static URLs to a callable which returns the HTTP response body for the given URL path.

2. Replace the code in the `cloudacademy/playground.py` file with the following.

```
1 from urllib.parse import parse_qs
2 from wsgiref.simple_server import make_server
3
4 class Application():
5     ''' A callable class serving as a WSGI application. '''
6
7     def __init__(self):
8         # A dictionary mapping path names to the function u
9         self.path_handlers = {}
10
11     def route(self, path):
12         ''' A callable decorator used to register a path ha
13
14         Args:
15             path | The path to register for the decorat
16
17         def wrap(handler, *args, **kwargs):
18             ''' Args:
19                 handler | The callable to call when
20                     provided to the route met
21
22                 The handler function isn'
23                 When the route method is
24                 is passed to this wrap fu
25
26                 args | Optional positional argum
27                 kwargs | Optional keyword argument
28
29             '''
30             # Store a tuple containing the handler callable
31             self.path_handlers[path] = (handler, args, kwar
```

about:blank

1h 45m

```
30         # Store a tuple containing the handler callable
31         self.path_handlers[path] = (handler, args, kwargs)
32         return wrap
33
34     def __call__(self, environ, start_response):
35         response_headers = [('Content-Type', 'text/plain')]
36         request_url_path = environ.get('PATH_INFO', '')
37
38         # Attempt to locate the callable for the current path
39         # If missing this is a 404 -- file not found -- error
40         if request_url_path not in self.path_handlers:
41             start_response('404 Not Found', response_headers)
42             return [f'{request_url_path} not found!'.encode('utf-8')]
43
44         try:
45             # Unpack the handler callable and arguments
46             handler, args, kwargs = self.path_handlers[request_url_path]
47             response_body = handler(*args, **kwargs)
48
49             # Call start_response only if the handler returns a response
50             start_response('200 OK', response_headers)
51             return [response_body]
52         except Exception as ex:
53             # If the handler fails, display a 500 error.
54             start_response('500 Internal Server Error', response_headers)
55             return [str(ex).encode('utf-8')]
56
57
```

The `route` method is a decorator used to map the decorated callable to the specified URL path. Decorator based routing is common to many Python web application frameworks.

3. Append the following WSGI application to the `cloudacademy/plavaround.py` file.

< Back

Start check

ChromeFileEditViewHistoryBookmarksProfilesTabWindowHelp

LiConnections - VA and DoDPython: Introduction to WSGIInstructions - platform

about:blank

1h 45m

3. Append the following WSGI application to the `cloudacademy/playground.py` file.

```
1 # Create an instance of the WSGI application so it can be u
2 # to decorate the response body functions.
3 app = Application()
4
5 # Register the index function to the default URL path.
6 # When this code is first read by the interpreter the route
7 # is called with a path of / and the decorated index functi
8 # callable used to generate the HTTP response body.
9 @app.route('/')
10 def index():
11     return b'Welcome! :)\n'
12
13 # Register the error function to the /error path.
14 # This will raise an error when called to test the 500 erro
15 @app.route('/error')
16 def error():
17     # The following code will raise a ZeroDivisionError
18     # https://docs.python.org/3/library/exceptions.html#Zer
19     return 1 / 0
20
21 if __name__ == '__main__':
22     server = make_server('', 5000, app)
23     server.serve_forever()
24
```

4. Start the WSGI server process.

```
python3 cloudacademy/playground.py
```

When this WSGI application is called it checks the WSGI server provided `PATH_INFO` value to determine if it matches one of the two registered URL paths. The forward

< Back

1h 45m

4. Start the WSGI server process.

```
python3 cloudacademy/playground.py
```

When this WSGI application is called it checks the WSGI server provided `PATH_INFO` value to determine if it matches one of the two registered URL paths. The forward slash at the end of the below URL (<http://localhost:5000/>) will match up to the `index` function.

5. Test the index URL path in the `curl` terminal.

```
curl http://localhost:5000/
```

`Welcome! :)`

If an error occurs when calling when calling the registered URL handler callable the exception handler returns a status of **500 Internal Server Error** and includes an error message.

6. Test the error URL path in the `curl` terminal.

```
curl -v http://localhost:5000/error
```

```
< Trying 127.0.0.1...
* TCP_NODELAY set
* Connected to localhost (127.0.0.1) port 5000 (#0)
> GET /error HTTP/1.1
> Host: localhost:5000
> User-Agent: curl/7.52.1
> Accept: */*
*
* HTTP/1.0, assume close after body
< HTTP/1.0 500 Internal Server Error
< Date: Thu, 23 Jun 2022 17:55:26 GMT
< Server: WSGIServer/0.2 CPython/3.9.9
< Content-type: text/plain
< Content-Length: 16
*
* Curl_http_done: called premature == 0

If a non-existent URL path is requested a status of **404 Not Found** is returned.

7. Test a non-existent URL path in the **curl** terminal.

```
curl -v http://localhost:5000/non-existent
```

```
* Trying 127.0.0.1...
* TCP_NODELAY set
* Connected to localhost (127.0.0.1) port 5000 (#0)
> GET /non-existent HTTP/1.1
> Host: localhost:5000
> User-Agent: curl/7.52.1
> Accept: */*
>
* HTTP/1.0, assume close after body
< HTTP/1.0 404 Not Found
< Date: Thu, 23 Jun 2022 16:26:29 GMT
< Server: WSGIServer/0.2 CPython/3.5.9
< Content-Type: text/plain
< Content-Length: 24
<
* Curl_http_done: called premature == 0
* Closing connection 0
/non-existent not found!
```

Modular WSGI applications can become middleware used to extend the functionality of a WSGI application. Self contained functionality such as parsing URL query strings is generalized enough to become middleware.

When the below `QueryStringParser` object is called it uses the `parse_qs` callable to parse the WSGI server-provided URL query string. The `parse_qs` callable returns a dictionary of key-value pairs from the query string. The `environ` argument is updated to store the parsed dictionary with the key **QUERY\_STRING\_PARSED**.

8. Add the following class definition to the `cloudacademy/playground.py` file underneath the `Application` definition.

```
1
2 class QueryStringParser():
```

8. Add the following class definition to the `cloudacademy/playground.py` file underneath the `Application` definition.

```
1
2 class QueryStringParser():
3     ''' A basic WSGI middleware example.
4
5         This middleware parses the URL query string convert
6         The dictionary is added to the environment variable
7         next WSGI application.
8     '''
9
10    def __init__(self, wsgi_app):
11        self.wsgi_app = wsgi_app
12
13    def __call__(self, environ, start_response):
14        environ['QUERY_STRING_PARSED'] = parse_qs(environ['
15        # Ensure the application is called.
16        return self.wsgi_app(environ, start_response)
17
```

If the `QueryStringParser` middleware runs first the `Application` object can use the parsed query string which was added to the dictionary bound to the name `environ`.

9. Replace the `__call__` method of the `Application` class.

**NOTE:** Ensure the indentation is correct after pasting.

```
1
2 def __call__(self, environ, start_response):
3     response_headers = [('Content-Type', 'text/plain')]
4
```

9. Replace the `__call__` method of the `Application` class.

NOTE: Ensure the indentation is correct after pasting.

```
1
2 def __call__(self, environ, start_response):
3     response_headers = [('Content-Type', 'text/plain')]
4     request_url_path = environ.get('PATH_INFO', '')
5
6     # Attempt to locate the callable for the current pa
7     # If missing this is a 404 -- file not found -- err
8     if request_url_path not in self.path_handlers:
9         start_response('404 Not Found', response_header
10        return [f'{request_url_path} not found!'.encode
11
12    try:
13        # Unpack the handler callable and arguments
14        handler, args, kwargs = self.path_handlers[requ
15        response_body = handler(*args, **kwargs)
16        # Call start_response only if the handler retur
17        start_response('200 OK', response_headers)
18        # Show the unparsed query string for comparison
19        query_str_orig = environ['QUERY_STRING']
20        # Get the parsed query string or return an empt
21        query_str_dict = environ.get('QUERY_STRING_PARS
22        # Build the multi-line query string display.
23        query_str_display = [f'key: {key}, value: {valu
24        query_str_display = '\n'.join(query_str_display
25        # Return both the response body, the original u
26        # and the parsed query string values.
27        return [
28            response_body,
29            f'The original query string: {query_str_ori
30            query_str_display.encode()
```

1h 45m

Back Start check

```

25         # Return both the response body, the original
26         # and the parsed query string values.
27         return [
28             response_body,
29             f'The original query string: {query_str_ori}
30             query_str_display.encode()
31         ]
32     except Exception as ex:
33         # If the handler fails, display a 500 error.
34         start_response('500 Internal Server Error', res
35         return [str(ex).encode()]
36

```

The `QueryStringParser` middleware parses the query string from `environ` and saves the parsed results as a dictionary. When the middleware runs first the parsed results will be available to the WSGI application. Wrapping the application with the middleware enables it to run first.

10. Replace the main code block.

```

1
2 if __name__ == '__main__':
3     server = make_server('', 5000, QueryStringParser(app))
4     server.serve_forever()
5

```

```

1 #!/usr/bin/env python
2 """WSGI application that returns the query string"""
3
4 from wsgiref.handlers import format_date_time
5 from datetime import datetime
6
7 def application(environ, start_response):
8     """A simple WSGI handler that returns the query string"""
9     # Get the query string from the environ
10    query_string = environ.get('QUERY_STRING', '')
11    # Format the date
12    date_time_string = format_date_time(datetime.utcnow())
13    # Return the query string and the date
14    response_body = f'Query String: {query_string}\nDate: {date_time_string}'
15    status = '200 OK'
16    response_headers = [('Content-type', 'text/plain')]
17    start_response(status, response_headers)
18    return [response_body.encode()]
19
20 if __name__ == '__main__':
21     # Import the necessary modules
22     from wsgiref.simple_server import make_server
23     # Create a WSGI server
24     server = make_server('', 5000, application)
25     # Serve the application
26     server.serve_forever()
27

```

1h 44m

```
from datetime import datetime
from wsgiref.handlers import format_date_time

def application(environ, start_response):
    """A simple WSGI application"""
    # Set the content type to text/html
    start_response('200 OK', [('Content-Type', 'text/html')])
    # Return the body of the response
    return ['<h1>Hello, World!</h1>']

if __name__ == '__main__':
    # Create the WSGI server and start it
    server = WSGIServer(('', 5000)), application
    server.serve_forever()
```

```
from datetime import datetime
from wsgiref.handlers import format_date_time

def application(environ, start_response):
    """A simple WSGI application"""
    # Set the content type to text/html
    start_response('200 OK', [('Content-Type', 'text/html')])
    # Return the body of the response
    return ['<h1>Hello, World!</h1>']

if __name__ == '__main__':
    # Create the WSGI server and start it
    server = WSGIServer(('', 5000)), application
    server.serve_forever()
```

11. Restart the WSGI server process.

Query string parameters appear at the end of a URL separated by a question mark ( `?` ). They're specified as key-value pairs of data separated by an equal sign ( `=` ). Multiple parameters are separated by an ampersand ( `&` ).

12. Test a URL query string in the **curl terminal**.

```
curl "http://localhost:5000/?greeting=Hello&target=World"
```

🌟 Proceed to the next step 🌟
